```

In this report we evaluate the relationship between relationship between bill depth and flipper length of penguins. The data come from [@gorman2014](#).

The diagram shows a side view of a penguin's head. A horizontal double-headed arrow labeled "Bill length" spans the width of the bill from the tip to the base. A vertical double-headed arrow labeled "Bill depth" measures the thickness of the bill at its widest point.

Table 1.1: Summary statistics

Table 1 matches Figure 2!

Mine Çetinkaya-Rundel
2020-11-10

In this report we evaluate the relationship between bill depth and flipper length of penguins. The data come from Gorman, Williams, and Fraser (2014).

Note: In the raw data, bill dimensions are recorded as "culmen length" and "culmen depth". The culmen is the dorsal ridge atop the bill.

The original dataset has 3 species (Adelie, Gentoo, and Chinstrap), but we will only work with Adelie and Chinstrap species.

minimal make

A minimal tutorial on make

I would argue that the most important tool for reproducible research is not [Sweave](#) or [knitr](#) but [GNU make](#).

Consider, for example, all of the files associated with a manuscript. In the simplest case, I would have an [R](#) script for each figure plus a [LaTeX](#) file for the main text. And then a [BibTeX](#) file for the references.

Compiling the final PDF is a bit of work:

- Run each R script through R to produce the relevant figure.
- Run latex and then bibtex and then latex a couple of more times.

And the R scripts need to be run before latex is, and only if they've changed.

A simple example

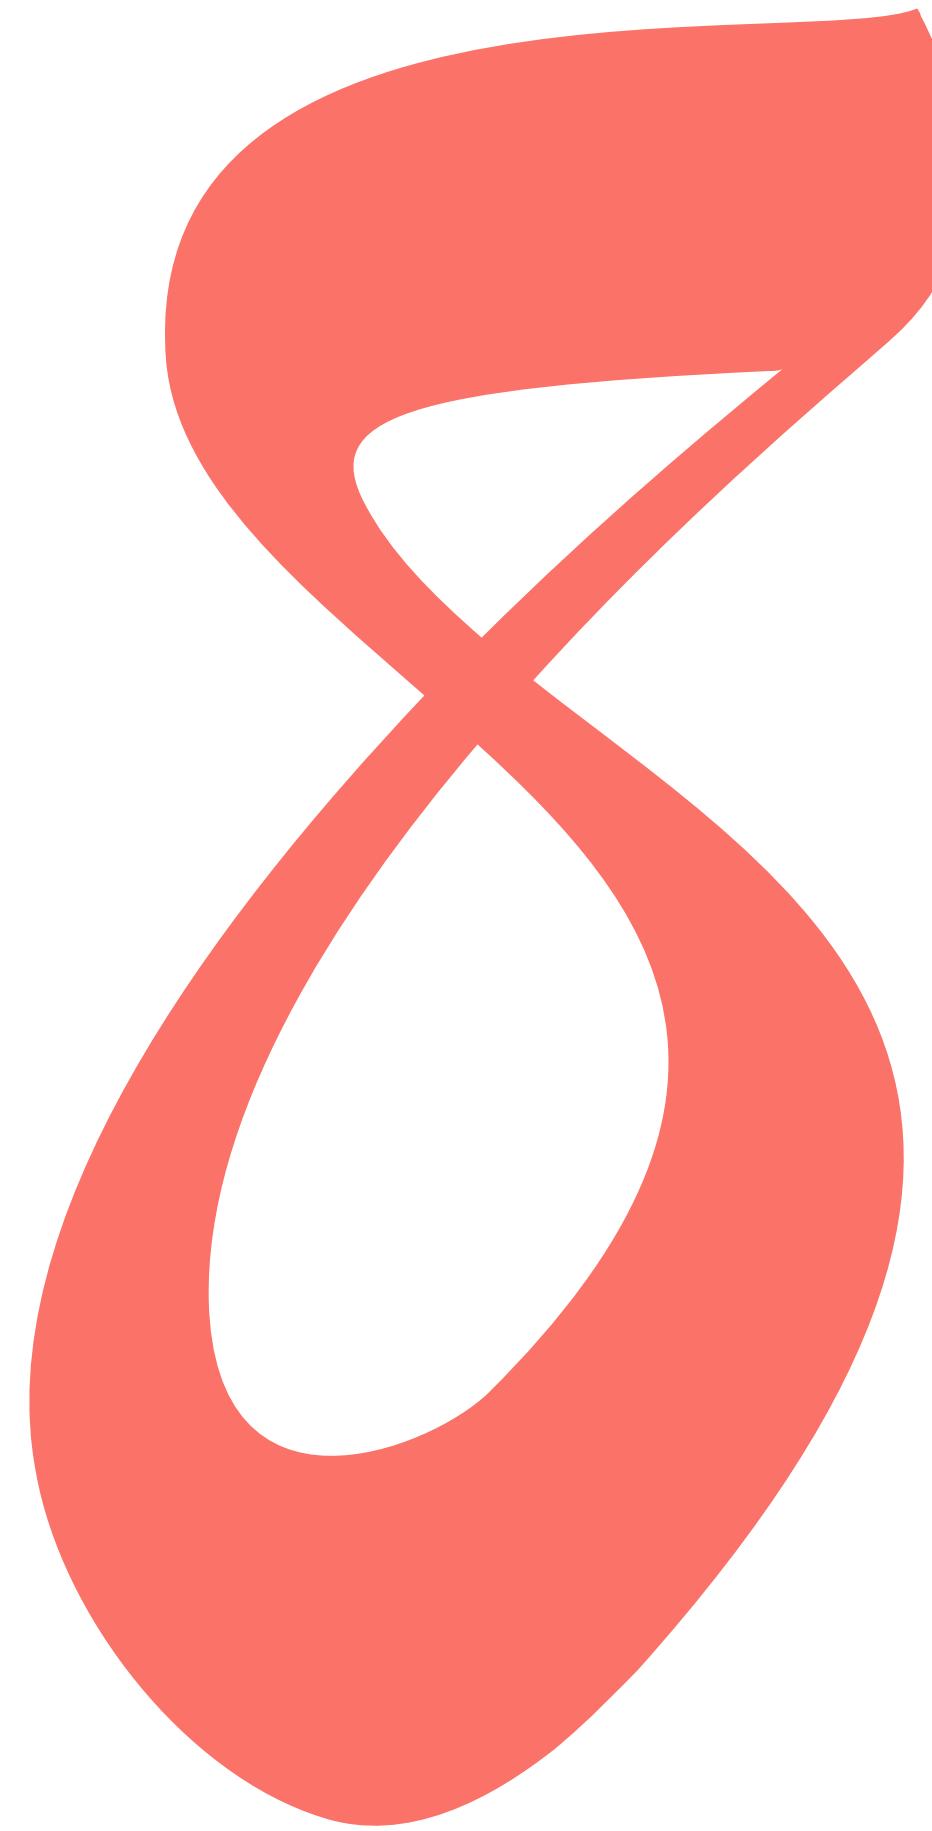

[GNU make](#) makes this easy. In your directory for the manuscript, you create a text file called `Makefile` that looks something like [the following](#) (here using [pdflatex](#)).

```
mypaper.pdf: mypaper.bib mypaper.tex Figs/fig1.pdf Figs/fig2.pdf
    pdflatex mypaper
    bibtex mypaper
    pdflatex mypaper
    pdflatex mypaper

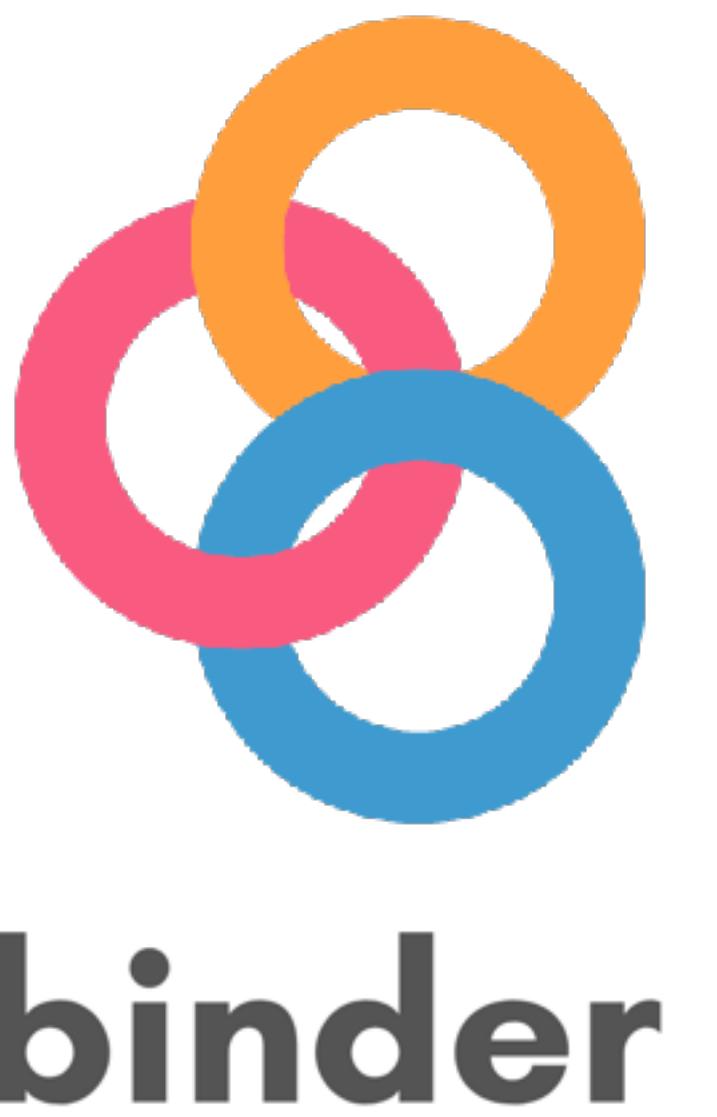

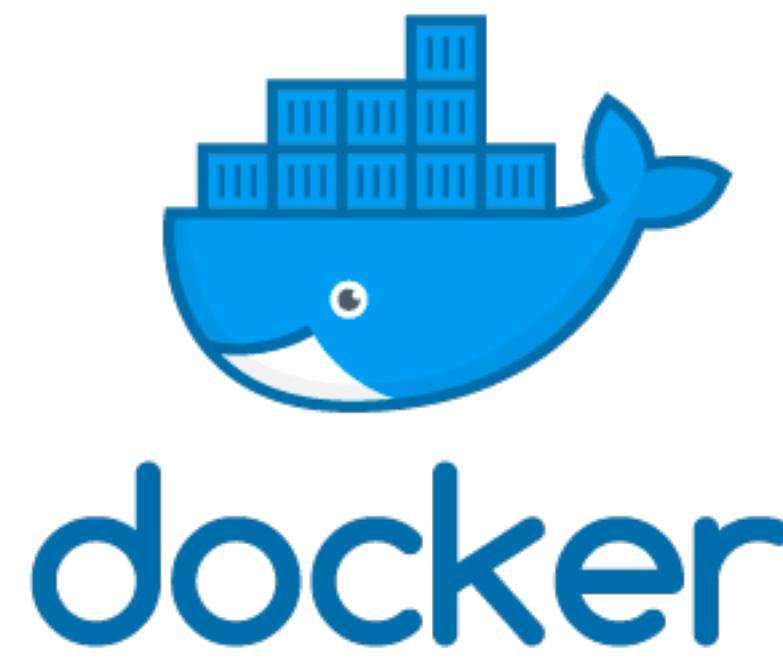

Figs/fig1.pdf: R/fig1.R
    cd R;R CMD BATCH fig1.R

Figs/fig2.pdf: R/fig2.R
    cd R;R CMD BATCH fig2.R
```

Each batch of lines indicates a file to be created (the *target*), the files it depends on (the *prerequisites*), and then a set of commands needed to construct the target from the dependent files. Note that the lines with the commands *must* start with a **tab** character (**not spaces**).

Author summary

Computers are now essential in all branches of science, but most researchers are never taught the equivalent of basic lab skills for research computing. As a result, data can get lost, analyses can take much longer than necessary, and researchers are limited in how effectively they can work with software and data. Computing workflows need to follow the same practices as lab projects and notebooks, with organized data, documented steps, and the project structured for reproducibility, but researchers new to computing often don't know where to start. This paper presents a set of good computing practices that every researcher can adopt, regardless of their current level of computational skill. These practices, which encompass data management, programming, collaborating with colleagues, organizing projects, tracking work, and writing manuscripts, are drawn from a wide variety of published sources from our daily lives and from our work with volunteer organizations that have delivered workshops to over 11,000 people since 2010.

Overview

We present a set of computing tools and techniques that every researcher can and should consider adopting. These recommendations synthesize inspiration from our own work, from the experiences of the thousands of people who have taken part in Software Carpentry and Data Carpentry workshops over the past 6 years, and from a variety of other guides. Our recommendations are aimed specifically at people who are new to research computing.

Introduction

Three years ago, a group of researchers involved in Software Carpentry and Data Carpentry wrote a paper called “Best Practices for Scientific Computing” [1]. That paper provided recommendations for people who were already doing significant amounts of computation in their research. However, as computing has become an essential part of science for all researchers, there is a larger group of people new to scientific computing, and the question then becomes, “where to start?”
